Responsive Grids and How to Use Them

I think I've become so accustomed to making a grid system for my physical design work that if I had to make one without a grid I would probably not know how to or where to start.

There is a comfort in having a grid that helps me stay organized especially when the project is a massive book spanning hundreds of pages. But when it comes to my digital work I usually forget to use a grid. There is a grid in my head when planning things out, so it doesn't look too odd when I actually begin to design, but I still don't have a grid. I think implementing a grid system is a bit harder with digital design than physical design. With physical design, I usually use InDesign that will show you a grid on every page in the document. But with digital design and its planning there really isn't a way to have a grid system on each of your frames so it's a lot harder to implement. The article did a really beautiful job at explaining the importance of a grid and I do completely agree with it, but the implementation is a lot more complicated. On top of that, everyone doesn't use the same program to design digitally, some people use Adobe XD others use Figma and etc, so the layouts and functionalities are different program to program. All that said, grids are very important!
